ABSTRACT

Investigations of the ichthyofauna of the San River are presented. Samples were collected twice in the river section between the Krasice and Radymino Villages in 1968 and once between the Łazów and Rudnik on the San Villages (Sarzyny District) in 1975. In the former investigated period the fish fauna was qualitatively and quantitatively rich: 25 species of 7 families were captured, chub (39,59%), nase (14,69%) and bleak (9,09%) being numerical abundance dominants. In the latter period 15 species of 5 families were identified. The biomass of chub was highest of all fish species in both sampling periods.
